## Sample Chemistry Question (Ch. 9-11) - CH 222

## Questions for Chapters Nine, Ten and Eleven:

1. When 7.00 grams of Helium and 14.0 grams of argon were mixed in a flask, the pressure was measured as 712 torr. What is the partial pressure of helium?
a. 593 torr
b. 356 torr
c. 833 torr
d. 1070 torr
e. 1420 torr
2. The empirical formula of a certain hydrocarbon is $\mathrm{CH}_{2}$. When 0.125 moles of this hydrocarbon are completely combusted with excess oxygen, it is observed that 11.2 L of $\mathrm{H}_{2} \mathrm{O}$ gas is produced at STP. What is the molecular formula of the unknown hydrocarbon?
a. $\mathrm{C}_{2} \mathrm{H}_{4}$
b. $\mathrm{C}_{2} \mathrm{H}_{3}$
c. $\mathrm{C}_{3} \mathrm{H}_{6}$
d. $\mathrm{C}_{4} \mathrm{H}_{8}$
e. $\mathrm{C}_{6} \mathrm{H}_{12}$
3. Lead (atomic mass $207.2 \mathrm{~g} / \mathrm{mol}$ ) crystallizes in a face-centered cubic arrangement. The radius of an atom of lead is $1.75 * 10^{-8} \mathrm{~cm}$. What is the density of lead?
a. $9.85 \mathrm{~g} / \mathrm{cm}^{3}$
b. $11.4 \mathrm{~g} / \mathrm{cm}^{3}$
c. $13.2 \mathrm{~g} / \mathrm{cm}^{3}$
d. $14.7 \mathrm{~g} / \mathrm{cm}^{3}$
e. $19.7 \mathrm{~g} / \mathrm{cm}^{3}$
4. Rank the compounds $\mathrm{NH}_{3}, \mathrm{CH}_{4}$, and $\mathrm{SiH}_{4}$ in order of increasing boiling point.
a. $\mathrm{NH}_{3}<\mathrm{CH}_{4}<\mathrm{SiH}_{4}$
b. $\mathrm{CH}_{4}<\mathrm{NH}_{3}<\mathrm{SiH}_{4}$
c. $\mathrm{NH}_{3}<\mathrm{SiH}_{4}<\mathrm{CH}_{4}$
d. $\mathrm{CH}_{4}<\mathrm{SiH}_{4}<\mathrm{NH}_{3}$
e. $\mathrm{SiH}_{4}<\mathrm{NH}_{3}<\mathrm{CH}_{4}$
5. A $1.34 \mathrm{M} \mathrm{NiCl}_{2}$ aqueous solution has a density of $1.12 \mathrm{~g} / \mathrm{cm}^{3}$. What is the molality of the solution?
a. 0.913 m
b. 1.42 m
c. 1.55 m
d. 2.55 m
e. 3.13 m
6. A solution is prepared by dissolving 0.500 g of non-dissociating solute in 12.0 g of cyclohexane. The freezing point depression of the solution is $8.94{ }^{\circ} \mathrm{C} . \mathrm{K}_{\mathrm{f}}$ for cyclohexane is $20.0^{\circ} \mathrm{C} / \mathrm{m}$. Calculate the molar mass of the solute.
a. $93.3 \mathrm{~g} / \mathrm{mol}$
b. $112 \mathrm{~g} / \mathrm{mol}$
c. $128 \mathrm{~g} / \mathrm{mol}$
d. $182 \mathrm{~g} / \mathrm{mol}$
e. $205 \mathrm{~g} / \mathrm{mol}$

## Here are the answers to the previous questions:

1. When 7.00 grams of Helium and 14.0 grams of argon were mixed in a flask, the pressure was measured as 712 torr. What is the partial pressure of helium?
a. 593 torr
b. 356 torr
c. 833 torr
d. 1070 torr
e. 1420 torr

Answer: Pressure is proportional to the quantity of moles present in a gas, and Dalton's Law of Partial Pressures says that the total pressure will be equal to the sum of the respective pressures. The mole fraction of the gas times the total pressure ( 712 torr) will give the respective pressures of the components. There are ( 7.00 $\mathrm{g} / 4.00 \mathrm{~g} / \mathrm{mol})=1.75 \mathrm{~mol} \mathrm{He}$ and $(14.0 \mathrm{~g} / 39.9 \mathrm{~g} / \mathrm{mol})=0.351 \mathrm{~mol} \mathrm{Ar}$. The mole fraction of He is $1.75 /(1.75$ $+0.351)=0.833$, and the partial pressure of helium will be $0.833 * 712$ torr $=\mathbf{5 9 3}$ torr, answer $(\mathbf{a})$.
2. The empirical formula of a certain hydrocarbon is $\mathrm{CH}_{2}$. When 0.125 moles of this hydrocarbon are completely combusted with excess oxygen, it is observed that 11.2 L of $\mathrm{H}_{2} \mathrm{O}$ gas is produced at STP. What is the molecular formula of the unknown hydrocarbon?
a. $\mathrm{C}_{2} \mathrm{H}_{4}$
b. $\mathrm{C}_{2} \mathrm{H}_{3}$
c. $\mathrm{C}_{3} \mathrm{H}_{6}$
d. $\mathrm{C}_{4} \mathrm{H}_{8}$
e. $\mathrm{C}_{6} \mathrm{H}_{12}$

Answer: First, find the moles of $\mathrm{H}_{2} \mathrm{O}$ produced, and then compare this number to 0.125 mol to find the ratio of " $\mathrm{H}_{2}$ " units in the hydrocarbon. Ex: ethane, $\mathrm{C}_{2} \mathrm{H}_{4}$, has two " $\mathrm{H}_{2}$ " units, so each mole of ethane will give two moles of water.

Also recall that STP implies a temperature of 273 K and 1 atm of pressure.
To find the moles of water: $\mathrm{n}=\mathrm{PV} / \mathrm{RT}=1 \mathrm{~atm} * 11.2 \mathrm{~L} / 0.082057 * 273 \mathrm{~K}=0.500 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}$.
The ratio $(0.500 / 0.125)=4$, and this is how many ${ } \mathrm{H}_{2}$ " units are present in the hydrocarbon. Since the empirical formula is $\mathrm{CH}_{2}$, we can imply there are four carbons with the four ${ } \mathrm{H}_{2}$ " units.

The final answer is (d), $\mathbf{C}_{4} \mathbf{H}_{8}$.
3. Lead (atomic mass $207.2 \mathrm{~g} / \mathrm{mol}$ ) crystallizes in a face-centered cubic arrangement. The radius of an atom of lead is $1.75 * 10^{-8} \mathrm{~cm}$. What is the density of lead?
a. $9.85 \mathrm{~g} / \mathrm{cm}^{3}$
b. $11.4 \mathrm{~g} / \mathrm{cm}^{3}$
c. $13.2 \mathrm{~g} / \mathrm{cm}^{3}$
d. $14.7 \mathrm{~g} / \mathrm{cm}^{3}$
e. $19.7 \mathrm{~g} / \mathrm{cm}^{3}$

Answer: Using unit analysis, we need an answer in $\mathrm{g} / \mathrm{cm}^{3}$. The numerator, g , comes from the molar mass of lead ( $207.2 \mathrm{~g} / \mathrm{mol}$ ), for the mol can be cancelled using Avogadro's number and by remembering that the face centered cubic requires four atoms per unit cell. The denominator, $\mathrm{cm}^{3}$, can be obtained from the equation: Edge $=4 *$ radius $/(2)^{1 / 2}$ and remembering that volume (in $\mathrm{cm}^{3}$ ) is equal to the cubed root of the edge.

So: numerator $(\mathrm{g})=207.2 \mathrm{~g} / \mathrm{mol} *\left(\mathrm{~mol} / 6.022 * 10^{23}\right.$ atoms $) *(4$ atoms $/$ cell $)=1.38 * 10^{-21} \mathrm{~g}$ denominator $\left(\mathrm{cm}^{3}\right)=(\text { edge })^{3}=\left(4 * 1.75 * 10^{-8} \mathrm{~cm} / 2^{1 / 2}\right)^{3}=1.21 * 10^{-22} \mathrm{~cm}^{3}$
Therefore, density $=1.38 * 10^{-21} \mathrm{~g} / 1.21 * 10^{-22} \mathrm{~cm}^{3}=\mathbf{1 1 . 4} \mathbf{~ g} / \mathbf{c m}^{3}$, answer (b).
4. Rank the compounds $\mathrm{NH}_{3}, \mathrm{CH}_{4}$, and $\mathrm{SiH}_{4}$ in order of increasing boiling point.
a. $\mathrm{NH}_{3}<\mathrm{CH}_{4}<\mathrm{SiH}_{4}$
b. $\mathrm{CH}_{4}<\mathrm{NH}_{3}<\mathrm{SiH}_{4}$
c. $\mathrm{NH}_{3}<\mathrm{SiH}_{4}<\mathrm{CH}_{4}$
d. $\mathrm{CH}_{4}<\mathrm{SiH}_{4}<\mathrm{NH}_{3}$
e. $\mathrm{SiH}_{4}<\mathrm{NH}_{3}<\mathrm{CH}_{4}$

Answer: Two factors affect boiling point: 1) mass (molar mass), and 2) strength of intermolecular forces. The larger the molar mass or intermolecular force, the higher the boiling point.

In terms of molar mass, the order would be $\mathrm{CH}_{4}(16 \mathrm{~g} / \mathrm{mol})<\mathrm{NH}_{3}(17 \mathrm{~g} / \mathrm{mol})<\mathrm{SiH}_{4}(32 \mathrm{~g} / \mathrm{mol})$. However, while $\mathrm{CH}_{4}$ and $\mathrm{SiH}_{4}$ have only induced dipole - induced dipole (ID-ID) forces, $\mathrm{NH}_{3}$ experiences hydrogen bonding forces, which is much stronger than the ID-ID force. Because the mass difference is not too large between $\mathrm{NH}_{3}$ and $\mathrm{SiH}_{4}$, we would expect the order to be $\mathbf{C H}_{4}<\mathbf{S i H}_{4}<\mathbf{N H}_{3}$, answer (d).
5. A $1.34 \mathrm{M} \mathrm{NiCl}_{2}$ aqueous solution has a density of $1.12 \mathrm{~g} / \mathrm{cm}^{3}$. What is the molality of the solution?
a. 0.913 m
b. 1.42 m
c. 1.55 m
d. 2.55 m
e. 3.13 m

Answer: Converting from molarity to molality (or weight percent or mole fraction) requires a solution density value. 1.34 M implies that there are 1.34 moles of $\mathrm{NiCl}_{2}$ in 1 L of solution.

We wish to calculate molality, which is the moles of solute per kg of solvent. We have 1.34 mol of solute in 1 L of solution, so if we can calculate the kg of solvent, we'll be good to go.
$1.34 \mathrm{~mol}^{*} 129.6 \mathrm{~g} / \mathrm{mol}=174 \mathrm{~g} \mathrm{NiCl}_{2}$
$1 \mathrm{~L} *(1000 \mathrm{~mL} / \mathrm{L}) *\left(\mathrm{~cm}^{3} / \mathrm{mL}\right) *\left(1.12 \mathrm{~g} / \mathrm{cm}^{3}\right)=1120 \mathrm{~g}$ of solution (which equals the g of $\mathrm{NiCl}_{2}$ and water)
$\mathrm{g} \mathrm{H}_{2} \mathrm{O}=1120 \mathrm{~g}-174 \mathrm{~g}=950 \mathrm{~g}$ water $*(1 \mathrm{~kg} / 1000 \mathrm{~g})=0.95 \mathrm{~kg}$ water
molality $=$ mol solute $/ \mathrm{kg}$ solvent $=1.34 \mathrm{~mol} / 0.95 \mathrm{~kg}=\mathbf{1 . 4} \mathbf{~ m}$, answer $(\mathbf{b})$.
6. A solution is prepared by dissolving 0.500 g of non-dissociating solute in 12.0 g of cyclohexane. The freezing point depression of the solution is $8.94^{\circ} \mathrm{C} . \mathrm{K}_{\mathrm{f}}$ for cyclohexane is $20.0^{\circ} \mathrm{C} / \mathrm{m}$. Calculate the molar mass of the solute.
a. $93.3 \mathrm{~g} / \mathrm{mol}$
b. $112 \mathrm{~g} / \mathrm{mol}$
c. $128 \mathrm{~g} / \mathrm{mol}$
d. $182 \mathrm{~g} / \mathrm{mol}$
e. $205 \mathrm{~g} / \mathrm{mol}$

Answer: molar mass $=\mathrm{g} / \mathrm{mol}$. We have 0.500 g for the mass, so we need to calculate the moles of solute present. We can use the freezing point depression equation, $\Delta \mathrm{T}=\mathrm{k}_{\mathrm{f}}^{*} \mathrm{~m}^{*} \mathrm{i}$.

Since the solute is non-dissociating, we can assume that $\mathrm{i}=1$.
Solve for $\mathrm{m}: ~ \mathrm{~m}=\Delta \mathrm{T} / \mathrm{k}_{\mathrm{f}}=8.94{ }^{\circ} \mathrm{C} / 20.0^{\circ} \mathrm{C} / \mathrm{m}=0.447 \mathrm{~m}=0.447 \mathrm{~mol}$ solute $/ \mathrm{kg}$ solvent (cyclohexane)
Since the problem used 12.0 g of solvent, $\{0.447 \mathrm{~mol} \text { solute } / \mathrm{kg} \text { solvent (cyclohexane) }\}^{*} 0.0120 \mathrm{~kg}$ solvent $=5.36^{*} 10^{-3} \mathrm{~mol}$ solute

Molar mass $=\mathrm{g}$ solute $/ \mathrm{mol}$ solute $=0.500 \mathrm{~g} / 5.36^{*} 10^{-3} \mathrm{~mol}=\mathbf{9 3 . 3} \mathbf{g} / \mathbf{m o l}$, answer ( $\mathbf{( a )}$.
