and

MAR

**Electron Transfer Reactions**

Electron transfer reactions are **oxidation-reduction** or **redox** reactions.

Redox reactions can result in the generation of an **electric current** or be caused by imposing an electric current.

Therefore, this field of chemistry is often called **ELECTROCHEMISTRY**.

MAR

MAR

**OXIDATION** - loss of electron(s) by a species; increase in oxidation number.

**REDUCTION** - gain of electron(s); decrease in oxidation number.

**OXIDIZING AGENT** - electron acceptor; species is reduced.

**REDUCING AGENT** - electron donor; species is oxidized.

**REDOX REACTIONS**

THE REDUCING AGENT IS OXIDIZED AND  
THE OXIDIZING AGENT IS REDUCED .net

Review of  
Terminology for  
Redox  
Reactions

MAR

**GER**

MAR

**LEO** says **GER**

**L**ose                      **G**ain  
**E**lectrons              **E**lectrons  
**O**xidized                **R**educed

Can also use "OIL RIG":  
OIL = "Oxidation is Losing" (electrons)  
RIG = "Reduction is Gaining" (electrons)

MAR

## OXIDATION-REDUCTION REACTIONS

### Direct Redox Reaction

Oxidizing and reducing agents in direct contact.

MAR

## Copper + Silver Ion

A clean piece of copper wire will be placed in a solution of silver nitrate,  $\text{AgNO}_3$ .

With time, the copper reduces  $\text{Ag}^+$  ions to silver metal crystals, and the copper metal is oxidized to copper ions,  $\text{Cu}^{2+}$ .

The blue color of the solution is due to the presence of aqueous copper(II) ions. (C. D. Winters)

MAR

## OXIDATION-REDUCTION REACTIONS

### Indirect Redox Reaction

A battery functions by transferring electrons through an external wire from the reducing agent to the oxidizing agent.

MAR

## Why Study Electrochemistry?

- Batteries
- Corrosion
- Industrial production of chemicals such as  $\text{Cl}_2$ ,  $\text{NaOH}$ ,  $\text{F}_2$  and  $\text{Al}$
- Biological redox reactions

The heme group

A rusted car

MAR

## Electrochemical Cells

An apparatus that allows a redox reaction to occur by transferring electrons through an external connector.

Product favored reaction  $\rightarrow$   
 voltaic or galvanic cell  $\rightarrow$   
 electric current created

Reactant favored reaction  $\rightarrow$   
 electrolytic cell  $\rightarrow$  electric current used to cause chemical change

Batteries are voltaic cells

MAR

## Famous Electrochemists

Alessandro Volta, 1745-1827, Italian scientist and inventor.

Luigi Galvani, 1737-1798, Italian scientist and inventor.

MAR

MAR

## Balancing Equations for Redox Reactions

Some redox reactions have equations that must be balanced by special techniques.

See: *Redox Reactions Handout*

MAR

## Balancing Equations

Consider the reduction of  $\text{Ag}^+$  ions with copper metal.

MAR

## Balancing Equations

**Step 1:** Divide the reaction into half-reactions, one for oxidation and the other for reduction.

**Step 2:** Balance each for mass. Already done in this case.

**Step 3:** Balance each half-reaction for charge by adding electrons.

MAR

## Balancing Equations

**Step 4:** Multiply each half-reaction by a factor that means the reducing agent supplies as many electrons as the oxidizing agent requires.

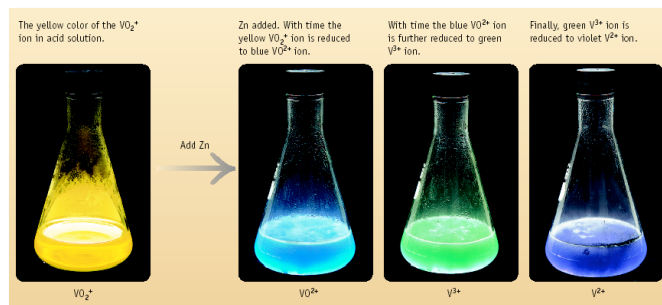

**Step 5:** Add half-reactions to give the overall equation.

The equation is now balanced for both charge and mass.

MAR

## Reduction of $\text{VO}_2^+$ with Zn

MAR

## Balancing Equations

Balance the following in *acidic* solution-

**Step 1:** Write the half-reactions

**Step 2:** Balance each half-reaction for mass.

MAR

## Balancing Equations

Balance the following in *acidic* solution-

**Step 1:** Write the half-reactions

**Step 2:** Balance each half-reaction for mass.

Add  $\text{H}_2\text{O}$  on O-deficient side and add  $\text{H}^+$  on other side for balancing hydrogen

MAR

## Balancing Equations

**Step 3:** Balance half-reactions for charge.

**Step 4:** Multiply by an appropriate factor.

**Step 5:** Add half-reactions

MAR

## Balancing Equations

Balance the following in *basic* solution-

**Step 1:** Write the half-reactions

**Step 2:** Balance each half-reaction for mass.

$\text{MnO}_4^{1-}$  = permanganate  
 $\text{MnO}_4^{2-}$  = manganate

MAR

## Balancing Equations

Balance the following in *basic* solution-

**Step 1:** Write the half-reactions

**Step 2:** Balance each half-reaction for mass.

Add H<sub>2</sub>O on H-deficient side and add OH<sup>-</sup> on other side for balancing oxygen

MAR

## Balancing Equations

**Step 3:** Balance half-reactions for charge.

**Step 4:** Multiply by an appropriate factor.

**Step 5:** Add half-reactions

Add H<sub>2</sub>O on H-deficient side and add OH<sup>-</sup> on other side for balancing oxygen *in basic solution*

MAR

## Alternate Basic Balancing Method

Balance basic reactions first with *acid*, then "neutralize" with OH<sup>-</sup>. *Previous example:*

**Step 1:** Write the half-reactions

**Step 2:** Balance each half-reaction for mass - use H<sup>+</sup> and/or H<sub>2</sub>O.

Add H<sup>+</sup> to H-deficient side and H<sub>2</sub>O to balance oxygen

MAR

## Alternate Basic Balancing Method

**Step 3:** Balance half-reactions for charge.

**Step 4:** Multiply by an appropriate factor.

**Step 5:** Add half-reactions

*This equation is balanced for pH < 7 but not base*

MAR

## Alternate Basic Balancing Method

**Step 6:** Neutralize H<sup>+</sup> by adding OH<sup>-</sup>.

H<sup>+</sup> and OH<sup>-</sup> make H<sub>2</sub>O.

Add OH<sup>-</sup> to *both* sides of equation

Use either method to balance basic redox reactions

Also see the *Redox Reactions Handout*

MAR

## Tips on Balancing Equations

- Determine the pH of the reaction.
- Never add O<sub>2</sub>, O atoms, or O<sup>2-</sup> to balance oxygen.
- Never add H<sub>2</sub> or H atoms to balance hydrogen.
- Be sure to write the correct charges on all the ions.
- Check your work at the end to make sure mass and charge are balanced.
- See: *Redox Reactions Handout*

MAR

### CHEMICAL CHANGE --> ELECTRIC CURRENT

Zn is oxidized and is the reducing agent  
 $Zn(s) \rightarrow Zn^{2+}(aq) + 2e^-$   
 Cu<sup>2+</sup> is reduced and is the oxidizing agent  
 $Cu^{2+}(aq) + 2e^- \rightarrow Cu(s)$

MAR

### CHEMICAL CHANGE --> ELECTRIC CURRENT

Oxidation:  $Zn(s) \rightarrow Zn^{2+}(aq) + 2e^-$   
 Reduction:  $Cu^{2+}(aq) + 2e^- \rightarrow Cu(s)$   
 -----  
 $Cu^{2+}(aq) + Zn(s) \rightarrow Zn^{2+}(aq) + Cu(s)$

MAR

### CHEMICAL CHANGE --> ELECTRIC CURRENT

To obtain a useful current, we separate the oxidizing and reducing agents so that electron transfer occurs through an external wire.

This is accomplished in a **GALVANIC** or **VOLTAIC** cell.

A group of such cells is called a **battery**.

MAR

Electrons travel through external wire.  
 Salt bridge allows anions and cations to move between electrode compartments, maintaining electrical neutrality.

Salt Bridge

MAR

Red Cat = REDuction  
 at the CATHode  
 $Cu^{2+} + 2e^- \rightarrow Cu$

### A Red Cat and An Ox

An Ox = OXidation  
 at the ANode  
 $Zn \rightarrow Zn^{2+} + 2e^-$

also remember:  
 oxidation = reducing agent  
 reduction = oxidizing agent

MAR

MAR

### SHORTHAND NOTATION for GALVANIC CELLS

$Cu^{2+}(aq) + Zn(s) \rightarrow Zn^{2+}(aq) + Cu(s)$   
 can also be written as:

phase boundary | salt bridge | phase boundary

Electrons flow this way  
 oxidation → reduction

FAT CAT = electrons flow From ANode To CATHode

### SHORTHAND NOTATION for GALVANIC CELLS

Example: Describe the following galvanic cell:

Solution:

The **anode** (oxidation) is:  $\text{Cu(s)} \rightarrow \text{Cu}^{2+}_{(\text{aq})} + 2 \text{e}^-$   
and  $[\text{Cu}^{2+}] = 1.0 \text{ M}$

The **cathode** (reduction) is:  $\text{Cl}_2(\text{g}) + 2 \text{e}^- \rightarrow 2 \text{Cl}^-_{(\text{aq})}$   
and  $[\text{Cl}^-] = 1.0 \text{ M}$  and  $P(\text{Cl}_2) = 1.0 \text{ atm}$

The cathode uses a **Platinum electrode** to transfer electrons to the  $\text{Cl}_{2(\text{g})}$ . The Pt does not react chemically with the electrons

MAR

Electrons move from anode to cathode in the wire. Anions (mostly) move through the salt bridge.

MAR

### Sign of Battery Terminals (Galvanic Cells Only)

Electrons flow away from the "negative" terminal (anode) and to the "positive" terminal (cathode) in Galvanic cells

Electrolytic cells use opposite signs

MAR

### Electromotive Force (emf)

Water only spontaneously flows one way in a waterfall.

Likewise, electrons only spontaneously flow one way in a redox reaction— from higher to lower potential energy.

MAR

### CELL POTENTIAL, E

Electrons are "driven" from anode to cathode by an electromotive force or **emf**.

For Zn/Cu cell, this is indicated by a **voltage** of **1.10 V** at 25 °C and when  $[\text{Zn}^{2+}]$  and  $[\text{Cu}^{2+}] = 1.0 \text{ M}$ .

MAR

Note that  $1 \text{ V} = 1 \text{ J/C}$ , more on this later

MAR

### CELL POTENTIAL, E

For Zn/Cu cell, voltage is **1.10 V** at 25 °C and when  $[\text{Zn}^{2+}]$  and  $[\text{Cu}^{2+}] = 1.0 \text{ M}$ .

This is the **STANDARD CELL POTENTIAL, E°**

**E°** (measured in Volts, V) is a quantitative measure of the tendency for reactants to proceed to products when all are in their standard states at 1.0 M and 25 °C.

### Calculating Cell Voltage

Balanced half-reactions can be added together to get overall, balanced equation.

If we know  $E^\circ$  for each half-reaction, we can calculate  $E^\circ$  for net reaction.

MAR

### CELL POTENTIALS, $E^\circ$

Cannot measure 1/2 reaction  $E^\circ$  directly. Therefore, measure it relative to a **STANDARD HYDROGEN CELL, SHE.**

(SHE = Standard Hydrogen Electrode)

$$E^\circ = 0.00\text{ V}$$

MAR

### Zn/SHE half cell

$E^\circ$  for the cell = **+0.76 V (measured)**

MAR

### Zn/SHE half cell

How to find the zinc half cell potential,  $E_{\text{Zn}}^\circ$ :

$$\text{so } E_{\text{Zn}}^\circ = E_{\text{net}}^\circ - E_{\text{H}^+}^\circ = 0.76 - 0.00 = +0.76\text{ V}$$

Therefore,  $E^\circ$  for  $\text{Zn} \rightarrow \text{Zn}^{2+}(\text{aq}) + 2\text{e}^-$  is **+0.76 V**

Zn is a **better** reducing agent than  $\text{H}_2$ .

MAR

### Cu/Cu<sup>2+</sup> and H<sub>2</sub>/H<sup>+</sup> Cell

MAR

### Cu/Cu<sup>2+</sup> and H<sub>2</sub>/H<sup>+</sup> Cell

Overall reaction is reduction of  $\text{Cu}^{2+}$  by  $\text{H}_2$  gas.

Measured  $E^\circ = +0.34\text{ V}$

Therefore,  $E^\circ$  for  $\text{Cu}^{2+} + 2\text{e}^- \rightarrow \text{Cu}$  is

$$+0.34\text{ V}$$

MAR

### Zn/Cu Electrochemical Cell

MAR

### Uses of E° Values

Half-reactions organized by relative ability to act as **oxidizing agents**

Use tables of **reduction potentials** in your textbook or problem set to predict the direction of redox reactions.

MAR

### Reversing Half Reactions

Reversing half reactions changes the sign but not the magnitude of E° values

Example:

Because E° tables listed as reductions, many negative E° values will appear

Negative E° values imply great oxidizers / reducing agents

Positive E° values imply great reducers / oxidizing agents

MAR

↑ reducing ability increases  
 OR  
 oxidizing agent capacity increases

Standard Reduction Potentials in Aqueous Solution		
at 25 °C*		
Reduction Half-Reaction		E° (V)
$F_2(g) + 2e^-$	$\rightarrow 2 F^-(aq)$	+2.87

↑ oxidizing ability increases  
 OR  
 reducing agent capacity increases

MAR

### Standard Redox Potentials, E°

Any substance on the right will reduce any substance higher than it on the left.

**Northwest-southeast rule:** product-favored reactions occur between reducing agent at southeast corner (anode) and oxidizing agent at northwest corner (cathode).

MAR

### Calculating E° (Michael's Method)

Flip one half-reaction from table (and E° value), then **add** oxidation and reduction values

Example: Determine E° for the following:

Solution: From redox tables we find:

Ni<sup>2+</sup> ok as written; need to flip Al<sup>3+</sup> reaction to:

So:  $E^\circ = 1.66 - 0.25 = 1.41 \text{ V}$

MAR

### Calculating E°

Calculate E°<sub>net</sub> for reaction between Cu and Ag<sup>+</sup> ions

Ag<sup>+</sup> ok as written; need to flip Cu<sup>2+</sup> reaction to:

E°<sub>net</sub> for Cu/Ag<sup>+</sup> reaction = 0.80 - 0.337 = +0.46 V

balanced reaction:  $\text{Cu} + 2\text{Ag}^+ \longrightarrow 2\text{Ag} + \text{Cu}^{2+}$

MAR

MAR

### E° for a Voltaic Cell

All ingredients are present.  
Which way does the reaction proceed?

### E° for a Voltaic Cell

From tables, you see:

Reaction occurs spontaneously when E° values are positive

Overall reaction:

$$E^{\circ} = E^{\circ}_{\text{cathode}} - E^{\circ}_{\text{anode}} = (-0.40 \text{ V}) - (-0.44 \text{ V}) = +0.04 \text{ V}$$

MAR

MAR

### More About Calculating Cell Voltage

Can I<sup>-</sup> ion reduce water? From tables:

Assuming reaction occurs as written,

$$E^{\circ}_{\text{net}} = E^{\circ}_{\text{red}} + E^{\circ}_{\text{ox}} = -0.828 \text{ V} - 0.535 \text{ V} = -1.363 \text{ V}$$

Minus E° means rxn occurs in opposite direction!

I<sup>-</sup> ion does not reduce water spontaneously!

### More About Calculating Cell Voltage

Can we make the I<sup>-</sup> ion reduce water?

Non-spontaneous (negative E°) reactions can be

"forced" to occur with external voltage

Voltage can be applied through battery, other voltaic cells, etc.

Applying 1.363 V to the above electrolytic cell will cause the I<sup>-</sup> reduce water - electrolysis

Are we cheating the second law of thermodynamics?

MAR

MAR

### E° and ΔG°

E° is related to ΔG°, the free energy change for the reaction.

$$\Delta G^{\circ} = -nFE^{\circ}$$

where F = Faraday constant = 9.6485 x 10<sup>4</sup> C/mol e<sup>-</sup>

and n is the number of moles of electrons transferred

Michael Faraday  
1791-1867

Memorize the value of F!  
Always use 96485 for F!

## $E^\circ$ and $\Delta G^\circ$

$$\Delta G^\circ = -nFE^\circ$$

For a **product-favored** reaction

Reactants  $\rightarrow$  Products

$\Delta G^\circ < 0$  and so  $E^\circ > 0$

$E^\circ$  is positive

For a **reactant-favored** reaction

Reactants  $\leftarrow$  Products

$\Delta G^\circ > 0$  and so  $E^\circ < 0$

$E^\circ$  is negative

MAR

## Quantitative Aspects of Electrochemistry

Consider electrolysis of aqueous silver ion.

If we could measure the moles of  $\text{e}^-$ , we could know the quantity of Ag formed.

But how to measure moles of  $\text{e}^-$ ?

$$\text{Current} = \frac{\text{charge passing}}{\text{time}} \quad I \text{ (amps)} = \frac{\text{coulombs}}{\text{seconds}}$$

MAR

### Quantitative Aspects of Electrochemistry

$$\text{Amps} = \frac{\text{coulombs}}{\text{seconds}}$$

A current of 1.50 amps (1.50 C/s) flows through a  $\text{Ag}^+(\text{aq})$  solution for 15.0 min. What mass of Ag metal is deposited?

**Solution**

(a) Calculate charge in Coulombs (C)

$$1.50 \text{ amps} = 1.50 \text{ C/s}$$

$$= (1.50 \text{ C/s})(60 \text{ s/min})(15.0 \text{ min}) = 1350 \text{ C}$$

MAR

### Quantitative Aspects of Electrochemistry

$$\text{Amps} = \frac{\text{coulombs}}{\text{seconds}}$$

A current of 1.50 amps (1.50 C/s) flows through a  $\text{Ag}^+(\text{aq})$  solution for 15.0 min. What mass of Ag metal is deposited?

**Solution**

(a) Charge = 1350 C

(b) Calculate moles of  $\text{e}^-$  used ( $F = 96,485 \text{ C/mol e}^-$ )

$$1350 \text{ C} \cdot \frac{1 \text{ mol e}^-}{96,485 \text{ C}} = 0.0140 \text{ mol e}^-$$

(c) Calc. quantity of Ag

$$0.0140 \text{ mol e}^- \cdot \frac{1 \text{ mol Ag}}{1 \text{ mol e}^-} = 0.0140 \text{ mol Ag or } 1.51 \text{ g Ag}$$

MAR

### Quantitative Aspects of Electrochemistry

The **anode reaction** in a lead storage battery is

If a battery delivers 1.50 amp, and you have 454 g of Pb, how long will the battery last?

**Solution**

a) 454 g Pb = 2.19 mol Pb

b) Calculate moles of  $\text{e}^-$

$$2.19 \text{ mol Pb} \cdot \frac{2 \text{ mol e}^-}{1 \text{ mol Pb}} = 4.38 \text{ mol e}^-$$

c) Calculate charge

$$4.38 \text{ mol e}^- \cdot 96,485 \text{ C/mol e}^- = 423,000 \text{ C}$$

MAR

### Quantitative Aspects of Electrochemistry

The **anode reaction** in a lead storage battery is

If a battery delivers 1.50 amp, and you have 454 g of Pb, how long will the battery last?

**Solution**

a) 454 g Pb = 2.19 mol Pb

b) Mol of  $\text{e}^-$  = 4.38 mol

c) Charge = 423,000 C

d) Calculate time  $\text{Time (s)} = \frac{\text{Charge (C)}}{I \text{ (amps)}}$

$$\text{Time (s)} = \frac{423,000 \text{ C}}{1.50 \text{ amp}} = 282,000 \text{ s} \quad \text{About } 78.3 \text{ hours}$$

MAR

## The Nernst Equation

**Q**, the reaction quotient, can be related to non standard cell potentials, **E**

**E** is related to **Q**, the reaction quotient, by:

$$E = E^\circ - (RT/nF) \ln Q$$

where **R** = Gas constant (8.3145 J/K mol)

**T** = Temperature (K)

**F** = Faraday constant

**E**<sup>°</sup> = standard cell potential

and **n** = the number of moles of electrons transferred

This is the **Nernst Equation** (*Handout*)

MAR

## The Nernst Equation

For Zn/Cu cell, voltage is **1.10 V** at 25 °C when  $[\text{Zn}^{2+}]$  and  $[\text{Cu}^{2+}] = 1.0 \text{ M}$

Adding  $\text{Cu}^{2+}(\text{aq})$  shifts reaction right (**Le Chatelier's Principle**), making reaction more spontaneous ( $\Delta G$ ) and **E**<sup>°</sup> **more positive**

MAR

## The Nernst Equation

Example: Find **E** when  $[\text{Zn}^{2+}] = 0.0010 \text{ M}$ ,  $P(\text{H}_2) = 0.10 \text{ atm}$  and  $\text{pH} = 0$  at 290. K.

**Solution:** Find **E**<sup>°</sup> for reaction under standard conditions first

Note that **n = 2**

MAR

## The Nernst Equation

Example: Find **E** when  $[\text{Zn}^{2+}] = 0.0010 \text{ M}$ ,  $P(\text{H}_2) = 0.10 \text{ atm}$  and  $\text{pH} = 0$  at 290. K.  $[\text{H}^+] = 1.0 \text{ M}$

**Solution**

Use Nernst Equation:

$$E = E^\circ - (RT/nF) \ln Q$$

$$E = 0.76 \text{ V} - (8.3145 \cdot 290. \text{ K} / 2 \cdot 96485) \ln Q$$

$$[\text{H}^+] = 10^{-\text{pH}} \text{ M} = 10^{-0} \text{ M} = 1.0 \text{ M}$$

$$Q = [\text{Zn}^{2+}] \cdot P_{\text{H}_2} / [\text{H}^+]^2 = [0.0010 \cdot 0.10 / (1.0)^2]$$

$$E = 0.76 \text{ V} + 0.12 \text{ V} = 0.88 \text{ V}$$

MAR

## E<sup>°</sup> and K

At Equilibrium (**K**), combine  $\Delta G$  expressions for **E**<sup>°</sup> and **K** to get:

$$E^\circ = \frac{RT}{nF} \ln K$$

If at 298 K, can use:

$$E^\circ = \frac{0.0257}{n} \ln K$$

Only valid at 298 K!

Find equilibrium constants from **E**<sup>°</sup> data!

MAR

## Electrochemical Processes in Batteries

A **battery** consists of self-contained voltaic cells arranged in series, so their individual voltages are added.

A **primary battery** cannot be recharged. The battery is "dead" when the cell reaction has reached equilibrium.

A **secondary battery** is rechargeable. Once it has run down, electrical energy is supplied to reverse the cell reaction and form more reactant.

MAR

## Dry Cell Battery

A **primary battery** - uses reactions that cannot be recharged

MAR

## Alkaline Battery

Nearly same reactions as in common dry cell, but under basic conditions.

MAR

## Silver Button Battery

MAR

## Mercury Button Battery

**Anode:**  
 Zn is reducing agent under basic conditions

MAR

## Lead-Acid Storage Battery

**Cathode (1.68 V):**

**Overall (cell) reaction (discharge):**

**Overall (cell) reaction (recharge):**

A **secondary battery** - can be recharged, reversible redox reactions

MAR

## Nickel-Cadmium Battery

**Anode (-):**

**Cathode (+):**

**Overall cell:**

MAR

## Lithium Battery

The primary lithium battery is widely used in watches, implanted medical devices, and remote-control devices.

Anode (oxidation):

Cathode (reduction):

Overall (cell) reaction:

MAR

## Lithium-Ion Battery

Anode (oxidation):

Cathode (reduction):

Overall (cell) reaction:

$$E_{\text{cell}} = 3.7 \text{ V}$$

The secondary (rechargeable) lithium-ion battery is used to power laptop computers, cell phones, and camcorders.

MAR

## Hydrogen Fuel Cell

In a fuel cell reactants enter the cell and products leave, generating electricity through controlled combustion. Reaction rates are lower in fuel cells than in other batteries, so an **electrocatalyst** is used to decrease the activation energy.

Anode (oxidation):

Cathode (reduction):

Overall (cell) reaction:

MAR

## Electrolysis

Using external electrical energy to produce chemical change in a nonspontaneous reaction

MAR

## A tin-copper reaction as a voltaic and electrolytic cell

MAR

## Electrolysis of Aqueous NaOH

Electric Energy  $\rightarrow$  Chemical Change

Anode (+)  $E^\circ = -0.40 \text{ V}$

Cathode (-)  $E^\circ = -0.83 \text{ V}$

$E^\circ$  for cell =  $-1.23 \text{ V}$

MAR

## Electrolysis

Electric Energy → Chemical Change

Electrolysis of molten NaCl. Here a battery "pumps" electrons from Cl⁻ to Na⁺. Polarity of electrodes is reversed from batteries.

MAR

## Electrolysis of Molten NaCl

Anode (+)  $E^\circ = -1.36 \text{ V}$   
 $2 \text{Cl}^- \rightarrow \text{Cl}_2(\text{g}) + 2\text{e}^-$

Cathode (-)  $E^\circ = -2.71 \text{ V}$   
 $\text{Na}^+ + \text{e}^- \rightarrow \text{Na}$

$E^\circ$  for cell =  $-4.07 \text{ V}$   
 External energy needed because  $E^\circ$  is (-).

MAR

## Electrolysis of Aqueous NaCl

Anode (+)  $E^\circ = -1.36 \text{ V}$

$2 \text{Cl}^- \rightarrow \text{Cl}_2(\text{g}) + 2\text{e}^-$

Cathode (-)  $E^\circ = -0.83 \text{ V}$

$2 \text{H}_2\text{O} + 2\text{e}^- \rightarrow \text{H}_2 + 2 \text{OH}^-$

$E^\circ$  for cell =  $-2.19 \text{ V}$

Note that  $\text{H}_2\text{O}$  is more easily reduced than  $\text{Na}^+$ .

Also,  $\text{Cl}^-$  is oxidized in preference to  $\text{H}_2\text{O}$  because of kinetics.

MAR

## Electrolysis of Aqueous NaCl

Cells like these are the source of NaOH and  $\text{Cl}_2$ .

In 2006

65 million tons  $\text{Cl}_2$

81 million tons NaOH

Also the source of NaOCl for use in bleach.

MAR

## Producing Aluminum

Charles Hall (1863-1914) developed electrolysis process, founded Alcoa (alcoa.com)

## End of Chapter 17

**Important Equations, Constants, and Handouts from this Chapter:**

**Redox Reactions:** oxidation, reduction, LEO, GER, oxidizing agent, reducing agent, anode, cathode, galvanic/voltaic cells, electrolysis (electrolytic cells), shorthand notation for galvanic cells, SHE electrode

- know how to balance redox reactions in acid or base conditions
- be able to calculate  $E^\circ$  and  $E$  for cells

$$\Delta G^\circ = -nFE^\circ$$

$$\text{Amps} = \frac{\text{coulombs}}{\text{seconds}}$$

$$E = E^\circ - (RT/nF) \ln Q$$

$$R = 8.3145 \text{ J mol}^{-1} \text{ K}^{-1}$$

$$F = 9.6485 \times 10^4 \text{ C/mol e}^-$$

$$E^\circ = \frac{RT}{nF} \ln K$$

- Thermodynamic Values and Electrochemical Cell Values (Problem Set #5)

MAR

**End of Chapter Problems: Test Yourself**

You will need the table of reduction potentials found in problem set #5

1. Write a balanced equation for the following half-reaction:  $\text{VO}_3^{-1}(\text{aq}) \rightarrow \text{V}^{2+}(\text{aq})$  (in acid)
2. Write a balanced equation for the following half-reaction:  $\text{Ag}(\text{s}) \rightarrow \text{Ag}_2\text{O}(\text{s})$  (in base)
3. Balance the following redox equation in acid:  $\text{Zn}(\text{s}) + \text{NO}_3^{-1}(\text{aq}) \rightarrow \text{Zn}^{2+}(\text{aq}) + \text{N}_2\text{O}(\text{g})$
4. Balance the following redox equation in base:  $\text{CrO}_4^{2-}(\text{aq}) + \text{SO}_3^{2-}(\text{aq}) \rightarrow \text{Cr}(\text{OH})_3(\text{s}) + \text{SO}_4^{2-}(\text{aq})$
5. Balance the following *unbalanced* equation in acid, then calculate the standard redox potential,  $E^\circ$ :  $\text{Cu}(\text{s}) + \text{NO}_3^{-1}(\text{aq}) \rightarrow \text{Cu}^{2+}(\text{aq}) + \text{NO}(\text{g})$
6. Calculate  $E^\circ$ ,  $\Delta G^\circ$  and the equilibrium constant for the following reaction:  $2 \text{Fe}^{3+}(\text{aq}) + 2 \text{I}^{-1}(\text{aq}) \rightarrow 2 \text{Fe}^{2+}(\text{aq}) + \text{I}_2(\text{aq})$

MAR

**End of Chapter Problems: Answers**

1.  $\text{VO}_3^{-1}(\text{aq}) + 6 \text{H}^+(\text{aq}) + 3 \text{e}^- \rightarrow \text{V}^{2+}(\text{aq}) + 3 \text{H}_2\text{O}(\text{l})$
2.  $2 \text{Ag}(\text{s}) + 2 \text{OH}^{-1}(\text{aq}) \rightarrow \text{Ag}_2\text{O}(\text{s}) + \text{H}_2\text{O}(\text{l}) + 2 \text{e}^-$
3.  $4 \text{Zn}(\text{s}) + 2 \text{NO}_3^{-1}(\text{aq}) + 10 \text{H}^+(\text{aq}) \rightarrow 5 \text{H}_2\text{O}(\text{l}) + 4 \text{Zn}^{2+}(\text{aq}) + \text{N}_2\text{O}(\text{g})$
4.  $2 \text{CrO}_4^{2-}(\text{aq}) + 5 \text{H}_2\text{O}(\text{l}) + 3 \text{SO}_3^{2-}(\text{aq}) \rightarrow 2 \text{Cr}(\text{OH})_3(\text{s}) + 4 \text{OH}^{-1}(\text{aq}) + 3 \text{SO}_4^{2-}(\text{aq})$
5.  $3 \text{Cu}(\text{s}) + 2 \text{NO}_3^{-1}(\text{aq}) + 8 \text{H}^+(\text{aq}) \rightarrow 2 \text{NO}(\text{g}) + 3 \text{Cu}^{2+}(\text{aq}) + 4 \text{H}_2\text{O}(\text{l})$ ,  $E^\circ = 0.62 \text{ V}$
6.  $E^\circ = 0.236 \text{ V}$ ,  $\Delta G^\circ = -45.5 \text{ kJ}$ ,  $K = 9 \times 10^7$

You will need the table of reduction potentials found in problem set #5
